5. Creating dummy variables

- The dataset has State ID, which has around 16 states. All states are not represented in equal proportions in the data. Creating dummy variables for all regions may also result in too many insignificant predictors. Nevertheless, only R1011, R1012, and R1013 are worth investigating further. Create a suitable strategy to create dummy variables with these restraints.

In [34]:
```
final_df["State ID"].value_counts()
```

Out[34]:
```

6. The variable NumberOfMajorSurgeries also appears to have string values. Apply a suitable method to clean up this variable.

In [40]:
```
final_df['NumberOfMajorSurgeries'].value_counts()
```

Out[40]:
```
No major surgery     1070
1                     961
2                     272
3                      22
Name: NumberOfMajorSurgeries, dtype: int64
```

- The NumberOfMajorSurgeries variable contain string value no major Surgery that mean simpli is 0 surgery so we will replace this value into int value equal to zero.

In [41]:
```
final_df['NumberOfMajorSurgeries'] = final_df['NumberOfMajorSurgeries'].replace('No major surgery', 0)
```

In [42]:
```
final_df['NumberOfMajorSurgeries'] = final_df["NumberOfMajorSurgeries"].astype(int)
```

7. Age appears to be a significant factor in this analysis. Calculate the patients' ages based on their dates of birth.

5 rows × 21 columns

8. The gender of the patient

- The gender of the patient may be an important factor in determining the cost of hospitalization. The salutations in a beneficiary's name can be used to determine their gender. Make a new field for the beneficiary's gender.

In [52]:
```
def gender(val):
    if "Ms." in val:
        return 0
    else:
        return 1
```

- Male = 1 & Female = 0

In [53]:
```
final_df["gender"] = final_df["name"].map(gender)
final_df.head(10)
```

Out[53]:

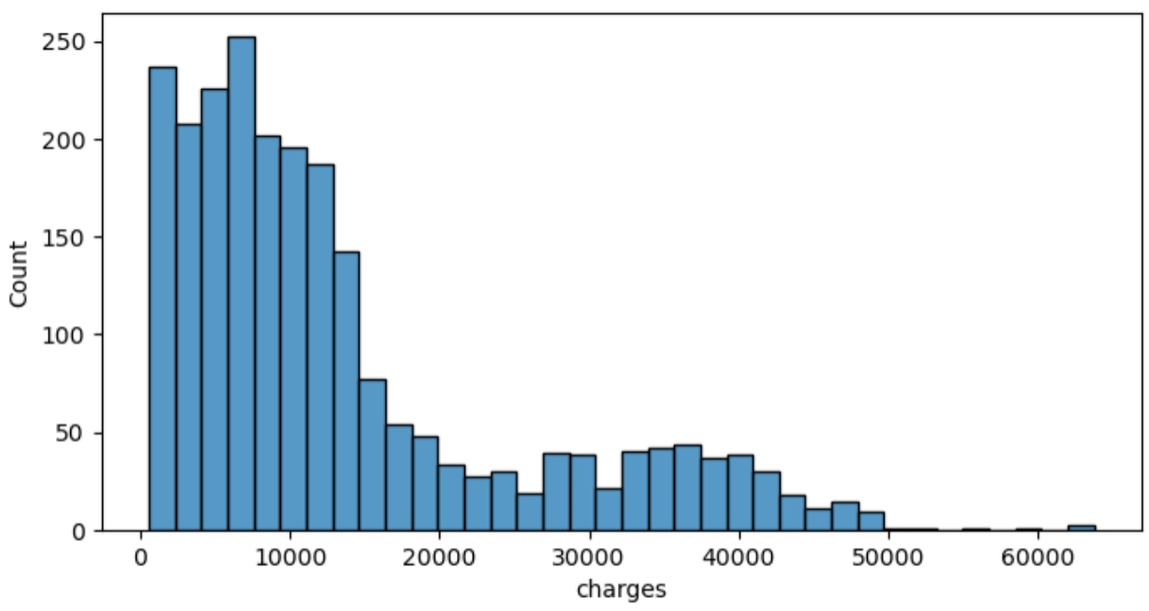
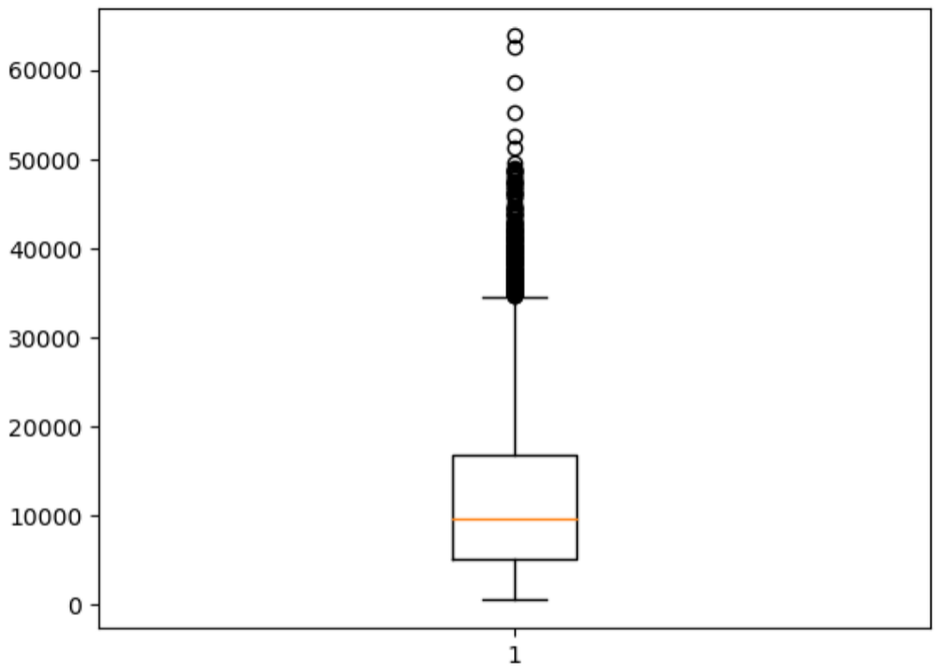
10 rows × 22 columns

9. visualizing the distribution of costs using a histogram, box and whisker plot, and swarm plot.

In [54]:
```
# Lets make the histogram for the cost distribution.
plt.figure(figsize=(8,4))
sns.histplot(final_df['charges'])
plt.show()
```



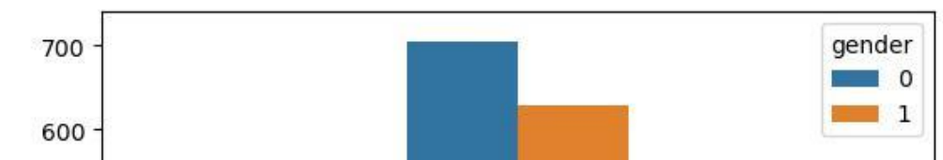
In [55]:
```
# Now visualize the cost distribution of the hospitals by box or whisker plot.
plt.boxplot(final_df['charges'])
plt.show()
```



In [56]:
```
# Now visualize the cost distribution of the hospitals by swarm plot.
plt.figure(figsize=(12,5))
sns.swarmplot(x='year', y='charges', hue="gender", data=final_df)
plt.xticks(rotation=90)
plt.show()
```

10. State how the distribution is different across gender and tiers of hospitals

In [57]:
```
sns.countplot(data = final_df, x='Hospital tier', hue= 'gender')
plt.show()
```



11. Creating a radar chart to showcase the median hospitalization cost for each tier of hospitals

In [58]:
```
print("median cost of tier 1 hospitals:", final_df[final_df["Hospital tier"]==1].charges.median())
print("median cost of tier 2 hospitals:", final_df[final_df["Hospital tier"]==2].charges.median())
print("median cost of tier 3 hospitals:", final_df[final_df["Hospital tier"]==3].charges.median())
```

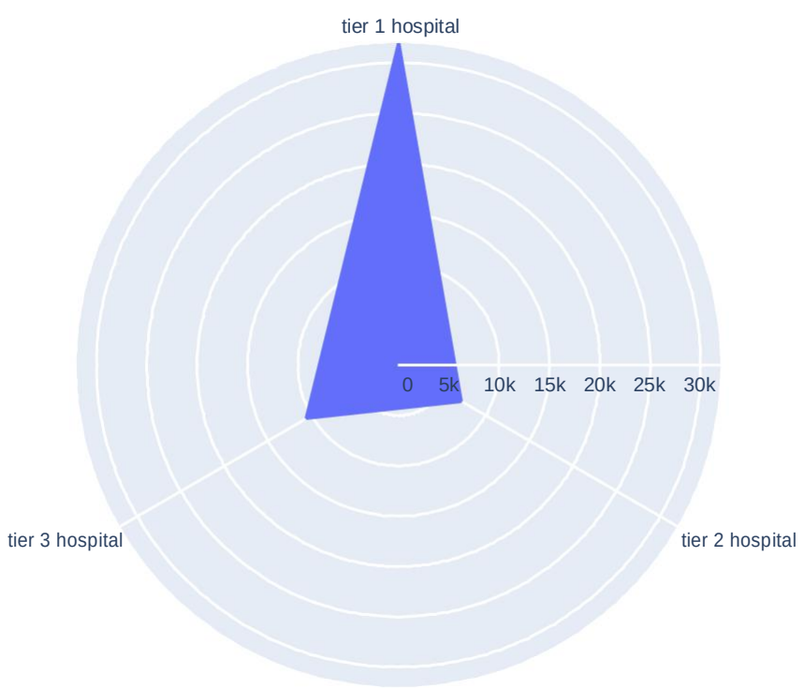
```
median cost of tier 1 hospitals: 32097.434999999998
median cost of tier 2 hospitals: 7168.76
median cost of tier 3 hospitals: 10676.83
```

In [59]:
```
df = pd.DataFrame(dict(r=[32097.43, 7168.76, 10676.83],theta=['tier 1 hospital','tier 2 hospital','tier 3 hospital']))
df
```

Out[59]:

	r	theta
0	32097.43	tier 1 hospital
1	7168.76	tier 2 hospital
2	10676.83	tier 3 hospital

In [60]:
```
import plotly.express as px
fig = px.line_polar(df, r='r', theta='theta', line_close=True)
fig.update_traces(fill='toself')
fig.show()
```



12. Creating a frequency table and a stacked bar chart to visualize the count of people in the different tiers of cities and hospitals

In [61]:
```
# Frequency table for count of the people according to the tier of city and hospitals.
final_df["Hospital tier"].value_counts()
```

Out[61]:
```
2    1334
3     691
1300
Name: Hospital tier, dtype: int64
```

In [62]:
```
# Frequency table for count of the people according to the tier of city and hospitals.
final_df["Hospital tier"].value_counts()
```

Out[62]:
```
2    1334
3     691
1300
Name: Hospital tier, dtype: int64
```

In [63]:
```
city_freq = final_df["City tier"].value_counts().rename_axis('City&hospital_tier').reset_index(name='city_counts')
```

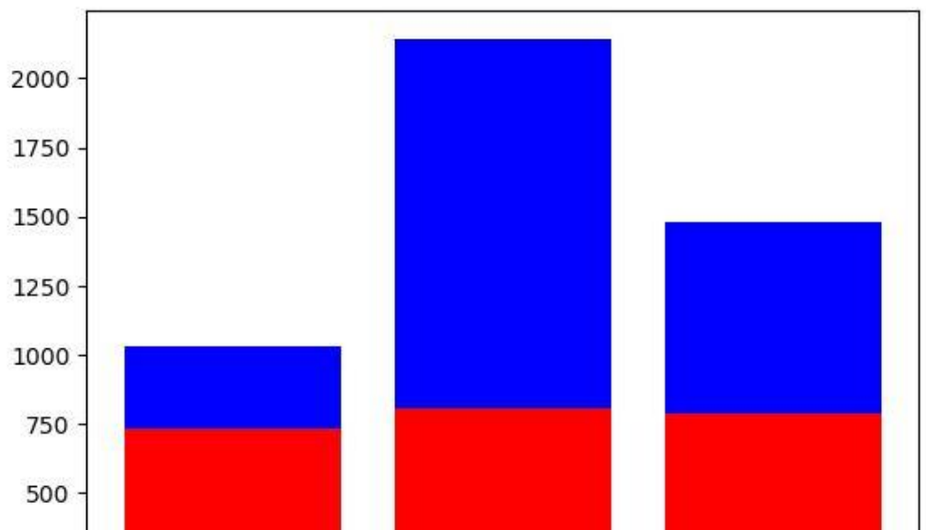
In [64]:
```
hospital_freq = final_df["Hospital tier"].value_counts().rename_axis('City&hospital_tier').reset_index(name='hospital_counts')
```

In [65]:
```
df = pd.merge(city_freq, hospital_freq, on = 'City&hospital_tier')
df.head()
```

Out[65]:

	City&hospital_tier	city_counts	hospital_counts
0	2	807	1334
1	3	789	691
2	1	729	300

In [66]:
```
plt.bar(df["City&hospital_tier"], df["city_counts"], color='r')
plt.bar(df["City&hospital_tier"], df["hospital_counts"], bottom=df["city_counts"], color='b')
plt.show()
```



13. Testing the following null hypotheses:-

In [67]:
```
from scipy.stats import ttest_1samp
```

In [68]:
```
# a. The average hospitalization costs for the three types of hospitals are not significantly different
print("median cost of tier 1 hospitals:", final_df[final_df["Hospital tier"]==1].charges.median())
print("median cost of tier 2 hospitals:", final_df[final_df["Hospital tier"]==2].charges.median())
print("median cost of tier 3 hospitals:", final_df[final_df["Hospital tier"]==3].charges.median())
```

```
median cost of tier 1 hospitals: 32097.434999999998
median cost of tier 2 hospitals: 7168.76
median cost of tier 3 hospitals: 10676.83
```

- Interpretation H0: the distributions of all samples are equal. || H1: the distributions of one or more samples are not equal

In [69]:
```
from scipy.stats import friedmanchisquare
data1 = [32097.43]
data2 = [7168.76]
data3 = [10676.83]
stat, p = friedmanchisquare(data1, data2, data3)
print('stat=%.3f, p=%.3f' % (stat, p))
if p > 0.05:
    print('Probably the same distribution')
else:
    print('Probably different distributions')
```

```
stat=2.000, p=0.368
Probably the same distribution
```

In [70]:
```
# b. The average hospitalization costs for the three types of cities are not significantly different
print("median cost of tier 1 city:", final_df[final_df["City tier"]==1].charges.median())
print("median cost of tier 2 city:", final_df[final_df["City tier"]==2].charges.median())
print("median cost of tier 3 city:", final_df[final_df["City tier"]==3].charges.median())
```

```
median cost of tier 1 city: 10027.15
median cost of tier 2 city: 8968.33
median cost of tier 3 city: 9880.07
```

In [71]:
```
data1 = [10027.15]
data2 = [8968.33]
data3 = [9880.07]
stat, p = friedmanchisquare(data1, data2, data3)
print('stat=%.3f, p=%.3f' % (stat, p))
if p > 0.05:
    print('Probably the same distribution')
else:
    print('Probably different distributions')
```

```
stat=2.000, p=0.368
Probably the same distribution
```

In [72]:
```
# c. The average hospitalization cost for smokers is not significantly different from the average cost for nonsmokers
print("median cost of smoker:", final_df[final_df["smoker"]==1].charges.median())
print("median cost of non smoker:", final_df[final_df["smoker"]==0].charges.median())
```

```
median cost of smoker: 34125.475
median cost of non smoker: 7537.16
```

In [73]:
```
from scipy.stats import kruskal
data1 = [34125.475]
data2 = [7537.16]
stat, p = kruskal(data1, data2)
print('stat=%.3f, p=%.3f' % (stat, p))
if p > 0.05:
    print('Probably the same distribution')
else:
    print('Probably different distributions')
```

```
stat=1.000, p=0.317
Probably the same distribution
```

- Interpretation:- H0 the two samples are independent. H1: there is a dependency between the samples.

In [74]:
```
# d. Smoking and heart issues are independent
from scipy.stats import chi2_contingency
table = [[final_df["Heart Issues"].value_counts()],[final_df["smoker"].value_counts()]]
stat, p, dof, expected = chi2_contingency(table)
print('stat=%.3f, p=%.3f' % (stat, p))
if p > 0.05:
    print('Probably independent')
else:
    print('Probably dependent')
```

```
stat=191.145, p=0.000
Probably dependent
```

Examine the correlation between predictors to identify highly correlated predictors. Use a heatmap to visualize this.

In [75]:
```
final_df.info()
```

```

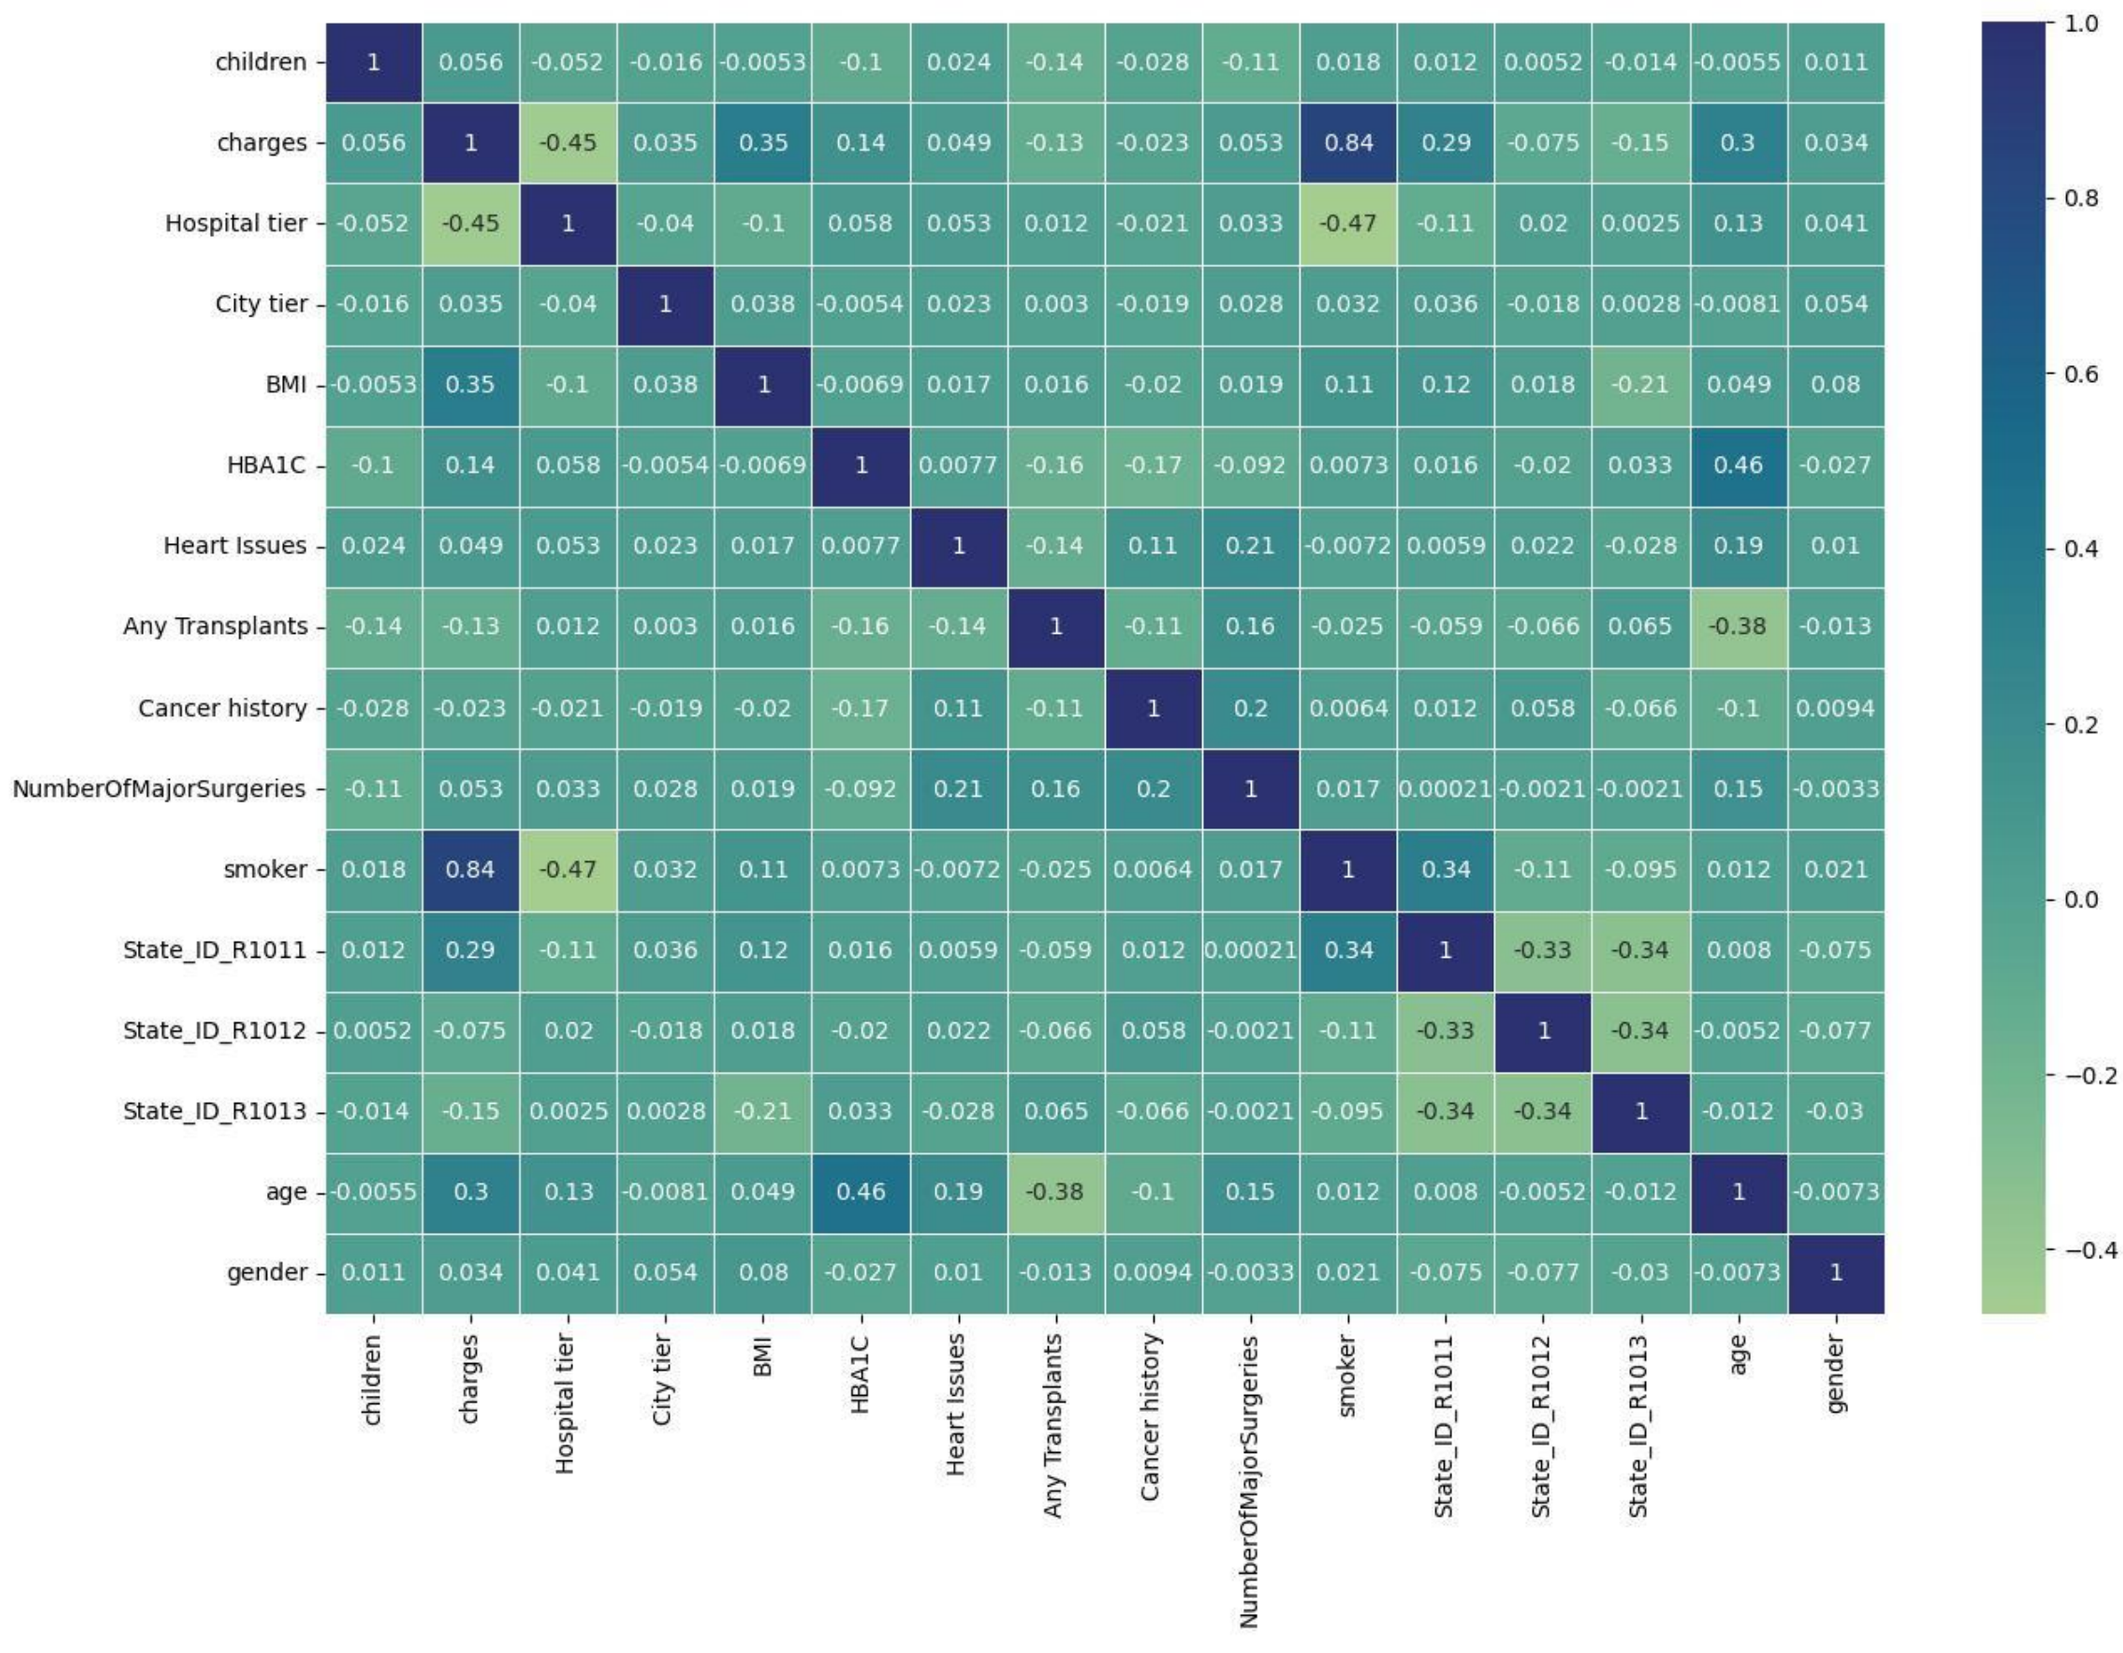
In [79]:
```
plt.figure(figsize=(15,10))
sns.heatmap(corr, annot=True, linewidth=.5, cmap="crest")
plt.show()
```



- From the above corelation its clear that somker variable is highly corealted to the output variable.

Develop and evaluate the final model using regression with a stochastic gradient descent optimizer. Also, ensure that you apply all the following suggestions:

In [80]:
```
# lets first seperate the input and output data.
x = final_df.drop(["charges"], axis=1)
y = final_df[['charges']]
```

In [81]:
```
# Lets split the data set into the training and testing data.
from sklearn.model_selection import train_test_split
```

In [82]:
```
x_train, x_test, y_train, y_test   = train_test_split(x,y, test_size=.20, random_state=10)
```

In [83]:

In [84]:

In [85]:

In [86]:

In [87]:

Out[87]:
```
# Now standardize the data.
from sklearn.preprocessing import StandardScaler
```

```
sc = StandardScaler()
```

```
x_train = sc.fit_transform(x_train)
x_test = sc.fit_transform(x_test)
```

In [88]:
```
from sklearn.linear_model import SGDRegressor
```

Out[88]:
```
from sklearn.model_selection import GridSearchCV
```

In [89]:
```
params = {'alpha': [0.0001, 0.001, 0.01, 0.05, 0.1, 0.2,0.3,0.4,0.5,
                    0.6,0.7,0.8,0.9,1.0,2.0,3.0,4.0,5.0,6.0,7.0,8.0,
In [90]:            9.0,10.0,20,50,100,500,1000],
          'penalty': ['l2', 'l1', 'elasticnet']}
```

Out[90]:
```
sgd = SGDRegressor()
```

In [91]:
```
# Cross Validation
folds = 5
```

Out[91]:
```

3. Use random forest and extreme gradient boosting for cost prediction, share your crossvalidation results, and calculate the variable importance scores

random forest

In [98]:
```
from sklearn.ensemble import RandomForestRegressor
```

In [99]:
```
# Instantiate model with 1000 decision trees
rf = RandomForestRegressor(n_estimators = 1000, random_state = 42)

# Train the model on training data
rf.fit(x_train, y_train)
```

Out[99]:
```
RandomForestRegressor(n_estimators=1000, random_state=42)
```

In [100…
```
score = rf.score(x_test,y_test)
score
```

Out[100]:
```
0.9222696338245824
```

In [101…
```
y_pred = rf.predict(x_test)
```

In [102…
```
rf_mae = mean_absolute_error(y_test, y_pred)
```

In [103…
```
rf_mae
```

Out[103]:
```
1870.3529629462323
```

Extreme gradient boosting

In [104…
```
from sklearn.ensemble import GradientBoostingRegressor
```

In [105…
```
# Instantiate model with 1000 decision trees
gbr = GradientBoostingRegressor(n_estimators = 1000, random_state = 42)

# Train the model on training data
gbr.fit(x_train, y_train)
```

Out[105]:
```
GradientBoostingRegressor(n_estimators=1000, random_state=42)
```

In [106…
```
score = gbr.score(x_test,y_test)
score
```

Out[106]:
```
0.9042734212625119
```

In [107…
```
y_pred = gbr.predict(x_test)
gbr_mae = mean_absolute_error(y_test, y_pred)
gbr_mae
```

Out[107]:
```
2375.8700944163274
```

4. Case scenario

In [117…
```
# First we need to calculate the age of the person.
date = str(19881228)
date1 = pd.to_datetime(date, format = "%Y%m%d")
```

In [118…
```
current_date = (dt.datetime.now())
current_date
```

Out[118]:
```
datetime.datetime(2023, 2, 13, 16, 54, 31, 143768)
```

In [120…
```
age = (current_date - date1)
age
```

Out[120]:
```
Timedelta('12465 days 16:54:31.143768')
```

In [121…
```
age = int(12421/365)
age
```

Out[121]:
```
34
```

In [122…
```
# now with the help of height and weight we will calculate the BMI.
height_m = 170/100
height_sq = height_m*height_m
BMI = 85/height_sq
np.round(BMI,2)
```

Out[122]:
```
29.41
```

In [123…
```
# Now lets gen
list = [[2,1,1,24.41,5.8,0,0,0,0,1,1,0,0,34,0]]
```

In [124…
```
df = pd.DataFrame(list, columns = ['children', 'Hospital tier', 'City tier', 'BMI', 'HBA1C','Heart Issues', 'Any Transplants',
                                   'Cancer history','NumberOfMajorSurgeries', 'smoker', 'State_ID_R1011', 'State_ID_R1012',
                                   'State_ID_R1013', 'age', 'gender'] )
df
```

Out[124]:

	children	Hospital tier	City tier	BMI	HBA1C	Heart Issues	Any Transplants	Cancer history	NumberOfMajorSurgeries	smoker	State_ID_R1011	State_ID_R1012	State_ID_R1013	age	gender
0	2	1	1	24.41	5.8	0	0	0	0	1	1	0	0	34	0

5. Find the predicted hospitalization cost using all models. The predicted value should be the mean of the five models' predicted values.

In [125…
```
Hospital_cost = []
```

In [126…
```
# Now lets predict the hospitalization cost through SGDRegressor
Cost1 = sgd.predict(df)
Hospital_cost.append(Cost1)
```

In [127…
```
# Now lets predict the hospitalization cost through Random Forest
Cost2 = rf.predict(df)
Hospital_cost.append(Cost2)
```

In [128…
```
# Now lets predict the hospitalization cost throug Extreme gradient Booster
Cost3 = gbr.predict(df)
Hospital_cost.append(Cost3)
```

In [129…
```
avg_cost = np.mean(Hospital_cost)
avg_cost
```

Out[129]:
```
104104.91171519303
```
